

# EXPLOIT WEB APPLICATION SECURITY USING DVWA

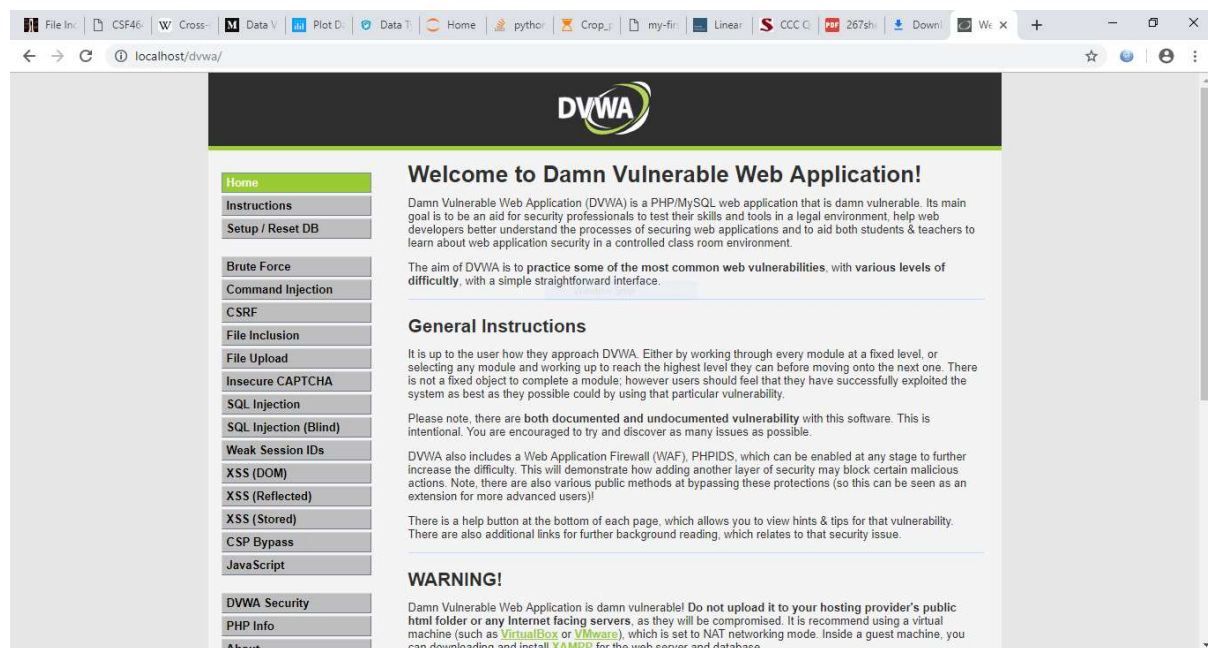

## WHAT IS DVWA?

- Damn Vulnerable Web App (DVWA) is a PHP/MySQL web application.
- Its main goals are to be an aid for security professionals to test their skills and tools in a legal environment,
- help web developers better understand the processes of securing web applications and aid teachers/students to teach/learn web application security in a class room environment.

## HOW TO INSTALL DVWA?

- Go to official site: <http://www.dvwa.co.uk/>
- Click on download.
- Put downloaded file in localhost folder (i.e. xampp\htdocs)
- Extract the file
- Start the server
- Run the local site in browser.
- Login with below credentials
- Username: 'admin' password: 'password'

## SCREENSHOT:

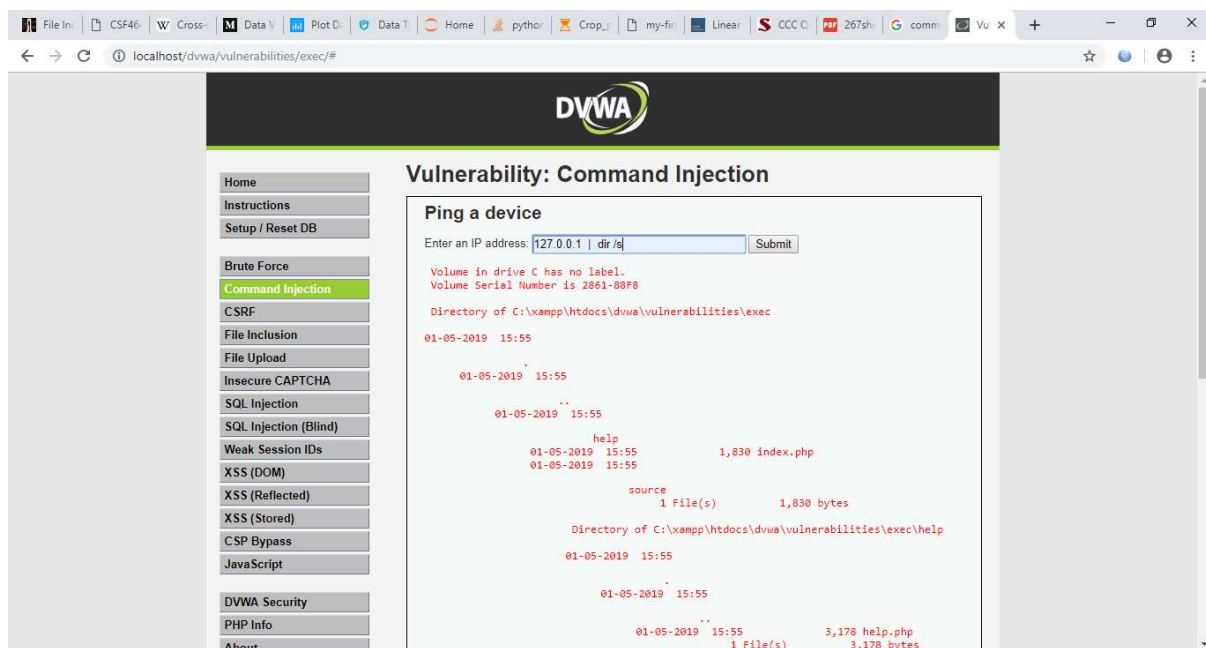

## COMMAND EXECUTION/INJECTION

- **DVWA - Command Injection.** Command injection is an attack in which the goal is **execution** of arbitrary **commands** on the host operating system via a vulnerable application.
- **Command injection** attacks are possible when an application passes unsafe user supplied data (forms, cookies, HTTP headers etc.) to a system shell.

### PURPOSE:

- The purpose of the command injection attack is to inject and execute commands specified by the attacker in the vulnerable application.
- In situations like this, the application, which executes unwanted system commands, is like a pseudo system shell, and the attacker may use it as an authorized system user.
- Note, the commands are executed with the same privileges as the application and/or web server.
- Command injection attacks are possible in most cases because of lack of correct input data validation, which can be manipulated by the attacker (forms, cookies, HTTP headers etc).

### SCREENSHOT:

## SQL INJECTION

- SQL injection (also known as SQL fishing) is a technique often used to attack data driven applications.
- This is done by including portions of SQL statements in an entry field in an attempt to get the website to pass a newly formed rogue SQL command to the database (e.g., dump the database contents to the attacker).
- SQL injection is a code injection technique that exploits a security vulnerability in an application's software.
- The vulnerability happens when user input is either incorrectly filtered for string literal escape characters embedded in SQL statements or user input is not strongly typed and unexpectedly executed.
- SQL injection is mostly known as an attack vector for websites but can be used to attack any type of SQL database.

### INSTRUCTIONS:

1. Input the below text into the User ID Textbox (See Picture).
2. %' or '0'='0
3. Click Submit

### NOTES:

- In this scenario, we are saying display all record that are **false** and all records that are **true**.
  - %' - Will probably not be equal to anything, and will be false.
  - '0'='0' - Is equal to true, because 0 will always equal 0.
- **Database Statement**
  - mysql> SELECT first\_name, last\_name FROM users WHERE user\_id = '% or '0'='0';
- **Know the Database name**
  - %' or 0=0 union select null, database()
- **Display all tables in information\_schema**
  - %' and 1=0 union select null, table\_name from information\_schema.tables #
- **Display all the user tables in information\_schema**
  - %' and 1=0 union select null, table\_name from information\_schema.tables where table\_name like 'user%'
- **For more information visit:**

## SCREENSHOT:

## FILE INCLUSION

- Allows an 'attacker' to include remote/local files into the web application.
- Remote [File Inclusion](#) (RFI) and Local File Inclusion (LFI) are vulnerabilities that are often found in poorly-written web applications.
- These vulnerabilities occur when a web application allows the user to submit input into files or upload files to the server.
- LFI vulnerabilities allow an attacker to read (and sometimes execute) files on the victim machine.
- This can be very dangerous because if the web server is misconfigured and running with high privileges, the attacker may gain access to sensitive information.
- If the attacker is able to place code on the web server through other means, then they may be able to execute arbitrary commands.
- RFI vulnerabilities are easier to exploit but less common. Instead of accessing a file on the local machine, the attacker is able to execute code hosted on their own machine.

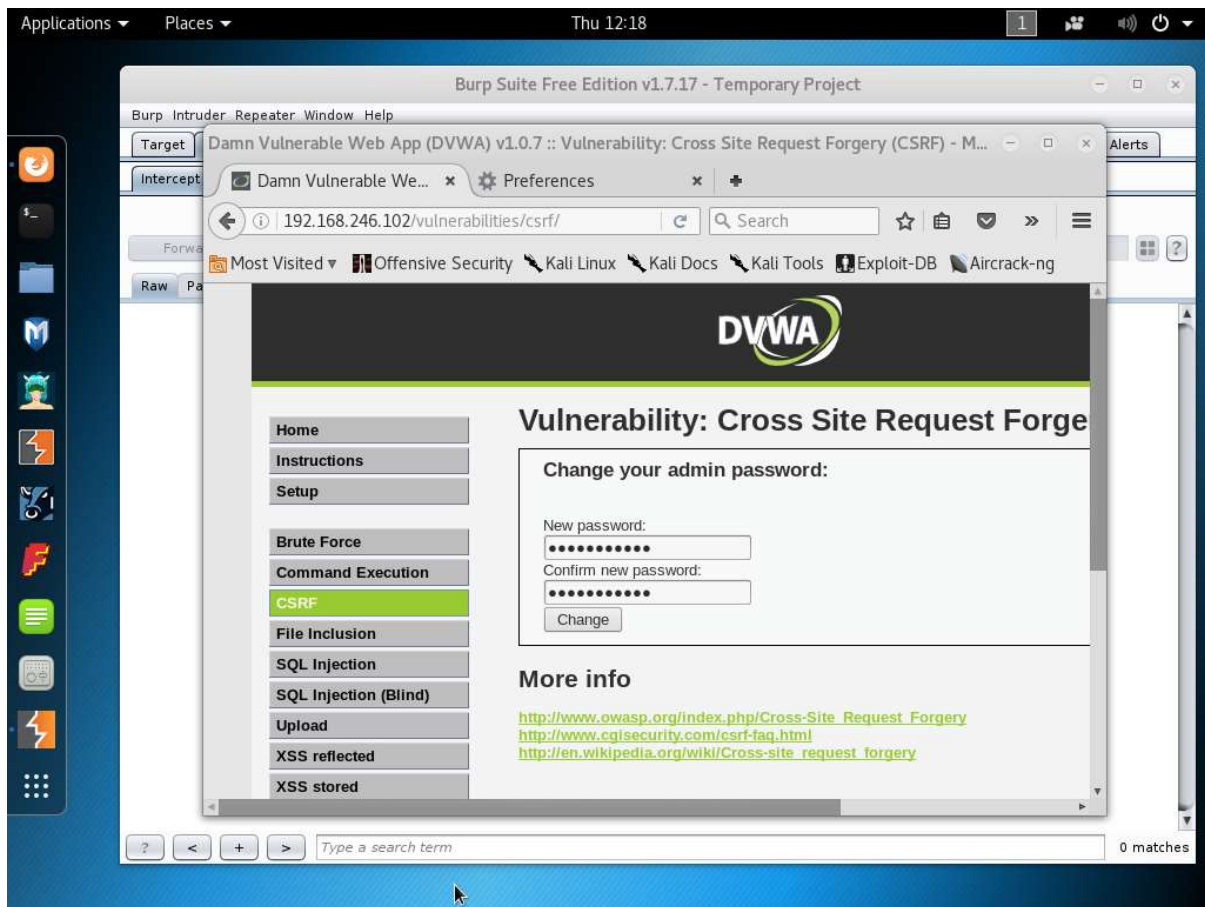

## SCREENSHOT:

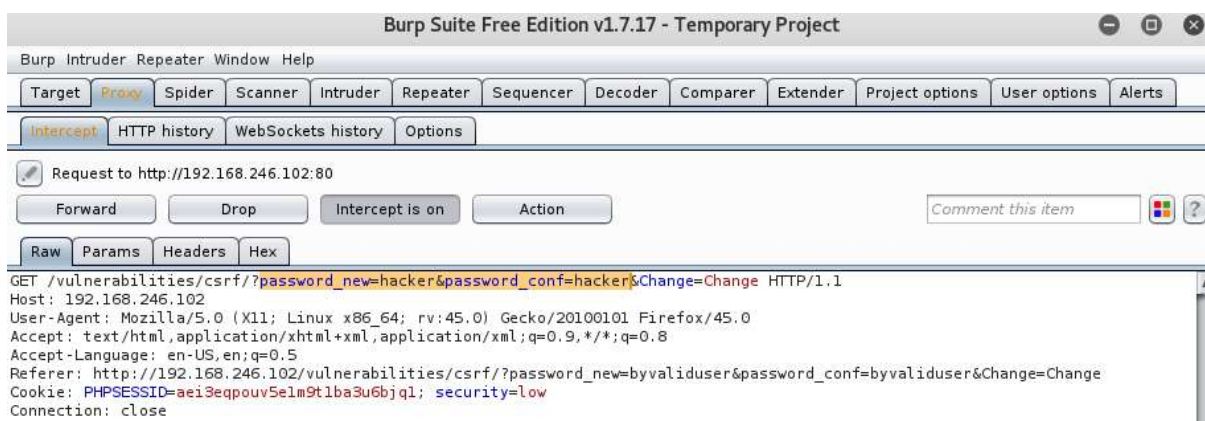

## CSRF/XXS

- **Cross-site request forgery**, also known as **one-click attack** or **session riding** and abbreviated as **CSRF** (sometimes pronounced *sea-surf*) or **XSRF**,
- is a type of malicious [exploit](#) of a [website](#) where unauthorized commands are transmitted from a [user](#) that the web application trusts.
- There are many ways in which a malicious website can transmit such commands; specially-crafted image tags, hidden forms, and [JavaScript](#) XMLHttpRequests,
- for example, can all work without the user's interaction or even knowledge. Unlike [cross-site scripting](#) (XSS), which exploits the trust a user has for a particular site, CSRF exploits the trust that a site has in a user's browser.

- Firstly, User will try to Enter New password and Hits on Change Button.

- Secondly, Burp suite will Capture the Request and Alters it as shown in image below : User enters Password as validuser:validuser but we edited as hacker:hacker.

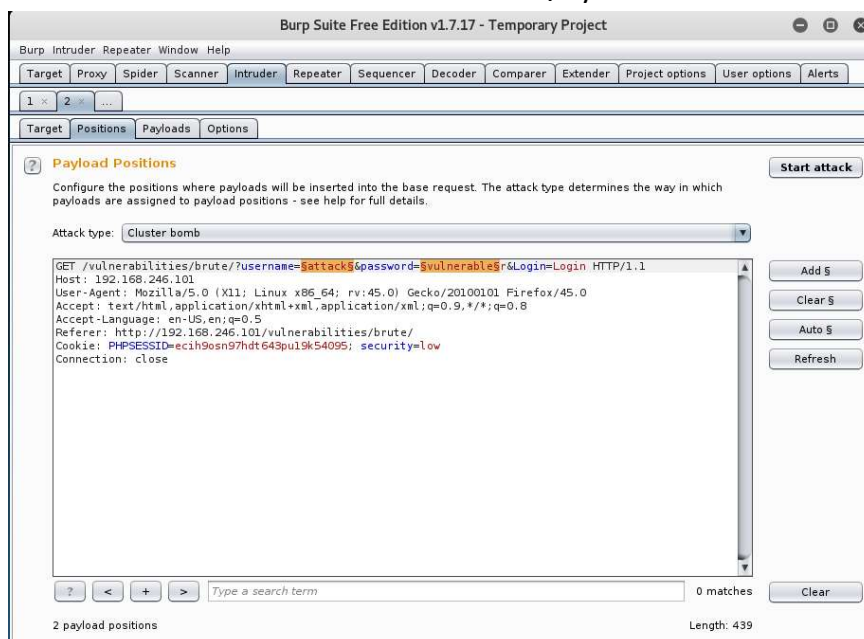

- **Query** Submitted by Middle-Man will executed Successfully.
- when the Authenticated User tries to Change Password again it throws Error message because data stored in database will be the password entered by Middle-man not by the Valid User.
- Acknowledgement show to User as "Password Changed", shown below

## BRUTE FORCE

- A **brute force attack** is a term in [cryptanalysis](#). It means trying to break a [coded cyphertext](#) by trying a lot of possibilities with fast [computers](#). For example, a large number of the possible [keys](#) are tried in the [key space](#). If successful, this [decrypts](#) the encrypted message.
- The theoretical possibility of a brute force attack is recognized by the [cryptographic](#) system designers. They work to make the cryptographic system very difficult for computers to break using brute force attack. For that reason, one of the definitions of "breaking" a cryptographic scheme is to find a method faster than a brute force attack.
- The selection of an appropriate [key length](#) depends on how difficult it will be to break it using a brute force attack. By [obfuscating](#) the data before [encryption](#), brute force attacks are less effective and more difficult to determine.
- In this challenge we have to find out whether it has been vulnerable to Brute Force Attack and IF yes, then Find out the Username and Password.
- We required a Tool here to Capture the Request-Response transactions of Web Application, We used Burpsuite Here to exploit this Vulnerability.
- Open Burpsuite and Set Proxy to **127.0.0.1:8080**
- Open Browser Setting and set proxy to **localhost:8080**
- Enter any credentials and capture those Packets in Burpsuite under Proxy tab, just forward it to **Intruder** (note down error reply which has to be entered in **Grep-Match field**)
- Analyze the Request and find Username and Password text filed enclosed with **\$\_\_\_\$**
- Mark username and Password Field with **\$** symbol.

- Select Attack Type = **Cluster Bomb**, Upload Payload 1 and 2
- Under Option tab Set Grep-Match as **Incorrect**
- Hit Button => Start Attack
- After Matching the Every Payload Entries, Burpsuite gives Username & password (Observes **untick** on Grep Field)
- Obtained Username and Password is "**admin**"& "**password**"

The screenshot shows the Burp Suite interface with the 'Intruder attack 5' window open. The 'Results' tab is selected, showing a table of attack results. The first entry (index 1) is highlighted, showing a successful match for 'admin' and 'password'. Below the table, the 'Request' tab is active, showing the HTTP request details.

Request	Payload1	Payload2	Status	Error	Timeout	Length	incorrect	Comment
0			200	<input type="checkbox"/>	<input type="checkbox"/>	4964	<input checked="" type="checkbox"/>	
1	admin	password	200	<input type="checkbox"/>	<input type="checkbox"/>	5008	<input type="checkbox"/>	
2	guest	password	200	<input type="checkbox"/>	<input type="checkbox"/>	4964	<input checked="" type="checkbox"/>	
3	user	password	200	<input type="checkbox"/>	<input type="checkbox"/>	4964	<input checked="" type="checkbox"/>	
4	staff	password	200	<input type="checkbox"/>	<input type="checkbox"/>	4964	<input checked="" type="checkbox"/>	
5	root	password	200	<input type="checkbox"/>	<input type="checkbox"/>	4964	<input checked="" type="checkbox"/>	
6	admin	Password	200	<input type="checkbox"/>	<input type="checkbox"/>	4964	<input checked="" type="checkbox"/>	
7	guest	Password	200	<input type="checkbox"/>	<input type="checkbox"/>	4964	<input checked="" type="checkbox"/>	
8	user	Password	200	<input type="checkbox"/>	<input type="checkbox"/>	4964	<input checked="" type="checkbox"/>	
9	staff	Password	200	<input type="checkbox"/>	<input type="checkbox"/>	4964	<input checked="" type="checkbox"/>	
10	root	Password	200	<input type="checkbox"/>	<input type="checkbox"/>	4964	<input checked="" type="checkbox"/>	
11	admin	password@123	200	<input type="checkbox"/>	<input type="checkbox"/>	4964	<input checked="" type="checkbox"/>	
12	guest	password@123	200	<input type="checkbox"/>	<input type="checkbox"/>	4964	<input checked="" type="checkbox"/>	
13	user	password@123	200	<input type="checkbox"/>	<input type="checkbox"/>	4964	<input checked="" type="checkbox"/>	

The 'Request' tab shows the following details:

```

GET /vulnerabilities/brute/?username=admin&password=password&Login=Login HTTP/1.1
